The average temperature coefficient for a solar panel is  $-0.32\%/^{\circ}\text{C}$ , which means for every degree above  $25^{\circ}\text{C}$ , a solar panel's output falls by a miniscule 0.32%. However, even if your solar panels were to reach the dizzying heights of  $50^{\circ}\text{C}$ , they would still be operating at roughly 92% of their original capacity - not a very significant loss at all.

The module price will fall from \$0.22 per Watt-peak of generation capacity, in summer 2023, to \$0.097/Wp in 2030. Global volume will rise by a factor of 11 and the price will more than halve.

That is why all solar panel manufacturers provide a temperature coefficient value (Pmax) along with their product information. In general, most solar panel coefficients range between minus 0.20 to minus 0.50 percent per degree Celsius. The closer this number is to zero, the less affected the solar panel is by the temperature rise.

The MPPT will only begin charging when there is sufficient solar radiation to cause the PV panel voltage to rise 5V above the Battery voltage. After that condition has been met it will continue charging as long as the PV voltage ...
